Skolkovo Institute of Science and Technology  
Bayesian Methods course

May 25, 2017

## Goal

Estimate posterior distributions of the model parameters from data

## Probabilistic Programming:

- Uncertainty in predictions;
- Uncertainty in representations;
- Regularizations with priors;
- Transfer learning;
- Hierarchical Neural Networks.

## Problem

Monte Carlo sampling is very slow for high-dimensional data

# Problem Statement

## Inference problem

Bayes' theorem states:  $\mathbb{P}(\boldsymbol{\theta} | \mathbf{X}) = \frac{\mathbb{P}(\mathbf{X} | \boldsymbol{\theta})\mathbb{P}(\boldsymbol{\theta})}{\mathbb{P}(\mathbf{X})}$

## Maximum A Posteriori (MAP) estimation

$$\boldsymbol{\theta}^* = \arg \max_{\boldsymbol{\theta}} [\ln \mathbb{P}(\boldsymbol{\theta} | \mathbf{X})] = \arg \max_{\boldsymbol{\theta}} [\ln \mathbb{P}(\mathbf{X} | \boldsymbol{\theta}) + \ln \mathbb{P}(\boldsymbol{\theta})]$$

## Monte Carlo approach:

- Metropolis-Hastings sampling;
- Gibbs sampling;
- No-U-Turn Sampling (NUTS).

## Goal

Approximate posterior distribution  $p(\theta|\mathbf{X})$  by function  $q(\theta)$  from parametric family.

$$\begin{array}{ccc} \ln p(\mathbf{X}) = \text{KL}(q||p) + \text{ELBO}(q) & & \\ \updownarrow & & \updownarrow \\ \int q(\theta) \ln \frac{q(\theta)}{p(\theta|\mathbf{X})} d\theta & & \int q(\theta) \ln \frac{p(\mathbf{X}, \theta)}{q(\theta)} d\theta \end{array}$$

Minimization of **KL(q||p)**  $\Leftrightarrow$  Maximization of **ELBO(q)**

# Automatic Differentiation Variational Inference (ADVI)

- Automatic transformation of constrained variables  $\zeta = T(\theta)$ ;  
Example:  $\theta \in \mathbb{R}_+ \Rightarrow \zeta = T(\theta) = \log \theta$ , then  $\zeta \in \mathbb{R}$ .
- $q(\zeta) = \mathcal{N}(\mu, \Sigma)$ , where  $\Sigma$  is diagonal;

$$\mu^*, \Sigma^* = \arg \max_{\mu, \Sigma} \text{ELBO}(q)$$

- Stochastic optimization;
- Reparametrization trick to apply automatic differentiation;
- Adaptive step-size.

## Neural Networks

Predict values of parameters by fitting complex model on the huge dataset

## Bayesian Neural Networks

Predict the parameters of the weights distributions from the dataset

<http://bit.ly/2rMQuDq>

# Experiments

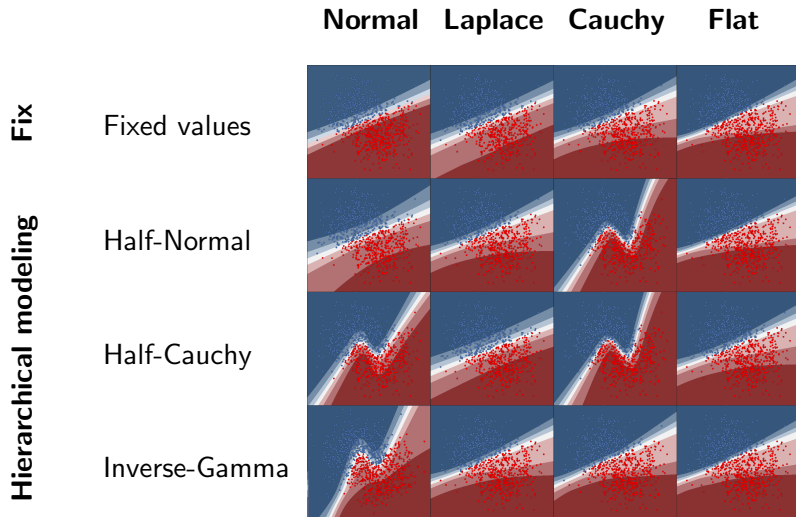

## Goals:

- investigate influence of different priors on the predictions
- visualize uncertainties in predictions
- analyze the model behaviour

## Datasets:

# Synthetic data

**Prior:** Cauchy  
**Hyperprior:**  
Inverse-Gamma  
**Accuracy:** 0.735

**Posterior  
Probability**

**Uncertainty**

**Prior:** Normal  
**Hyperprior:**  
Inverse-Gamma  
**Accuracy:** 0.851

# Hierarchical modelling

**Prior:** Normal

**Prior:** Laplace

**Hyperprior:**

Fixed values

**Hyperprior:**

Inverse-Gamma

# Laplace sparsity

## Conclusions:

- Accuracy score: 97.7%;
- Variance is much higher for misclassified pictures;
- Model is not always confident.

Misclassified pictures with **zero expected error rate**:

True	Prediction	True	Prediction	True	Prediction
7	0	9	7	5	6

Pictures with the **lowest confidence**:

True	Prediction	True	Prediction	True	Prediction
4	0	6	8	1	1

# Conclusion

- Posterior distribution helps to make conclusions about uncertainties
- Variational inference allows to approximate posterior distribution for high-dimensional data
- Hierarchical models have more degrees of freedom
